

Step-1

The matrix A contains n eigenvalues $\hat{I}_{\gg 1}, \hat{I}_{\gg 2}, \dots, \hat{I}_{\gg n}$. Since, the matrix A is not a zero matrix, at least one of the eigenvalues of A must be nonzero.

Without loss of generality, let $\hat{I}_{\gg n}$ be a non zero eigenvalue.

Thus, we have $Ax = \lambda_n x$, where $\lambda_n \neq 0$ and $x \neq 0$.

Step-2

Let us apply the product $(A - \lambda_1 I)(A - \lambda_2 I) \cdots (A - \lambda_n I)$ to the vector x . Thus, we get

$$\begin{aligned} ((A - \lambda_1 I)(A - \lambda_2 I) \cdots (A - \lambda_n I))x &= ((A - \lambda_1 I)(A - \lambda_2 I) \cdots)(A - \lambda_n I)x \\ &= ((A - \lambda_1 I)(A - \lambda_2 I) \cdots)(Ax - \lambda_n Ix) \\ &= ((A - \lambda_1 I)(A - \lambda_2 I) \cdots)(\lambda_n x - \lambda_n x) \\ &= ((A - \lambda_1 I)(A - \lambda_2 I) \cdots)(0) \\ ((A - \lambda_1 I)(A - \lambda_2 I) \cdots (A - \lambda_n I))x &= 0 \end{aligned}$$

Step-3

Thus, we have shown that $\boxed{(A - \lambda_1 I)(A - \lambda_2 I) \cdots (A - \lambda_n I) = 0}$.
