Step-1

We need to explain why $\frac{\left| \frac{\lambda_n}{\lambda_{n-1}} \right|}{\left| \frac{\lambda_n}{\lambda_{n-1}} \right|}$ controls the convergence of the usual power method. Construct a matrix A for which this method does not converge.

The power method with the initial guess u_0 can be seen as $u_{k+1} = Au_k$

Also, if λ_k is the Eigen value and u_k is the respective Eigen vector, then $Au_k = \lambda_k u_k$

Using
$$u_1 = Au_0, u_2 = Au_1 = A^2u_0, ..., u_{k+1} = A^ku_0$$
,

Step-2

If $x_1, x_2, ..., x_n$ are the Eigen vectors corresponding to the Eigen values $\lambda_1, \lambda_2, ..., \lambda_n$, then $u_k = c_1 \lambda_1^k x_1 + c_2 \lambda_2^k x_2 + ... + c_n \lambda_n^k x_n$ such that $|\lambda_1| \le |\lambda_2| \le ... \le |\lambda_n|$.

Dividing throughout by λ_n^k ,

So,

$$\begin{split} \frac{u_k}{\lambda_n^{\ k}} &= c_1 \, \frac{\lambda_1^{\ k}}{\lambda_n^{\ k}} \, x_1 + c_2 \, \frac{\lambda_2^{\ k}}{\lambda_n^{\ k}} \, x_2 + \ldots + c_{n-1} \, \frac{\lambda_{n-1}^{\ k}}{\lambda_n^{\ k}} \, x_{n-1} + c_n x_n \\ &= c_1 \bigg(\frac{\lambda_1}{\lambda_n} \bigg)^k \, x_1 + c_2 \bigg(\frac{\lambda_2}{\lambda_n} \bigg)^k \, x_2 + \ldots + c_{n-1} \bigg(\frac{\lambda_{n-1}}{\lambda_n} \bigg)^k \, x_{n-1} + c_n x_n \end{split}$$

The vectors u_k point more and more accurately towards the direction of x_n .

Step-3

Their convergence factor is the ratio,

 $r = \frac{|\lambda_{n-1}|}{|\lambda_n|}$ If is nearly equal to 1, then the convergence of Eigen value will be very slow.

 $\frac{\left|\lambda_{i}\right|}{\left|\lambda_{1}\right|} < 1 \qquad \frac{u_{k}}{\left|\lambda_{n}\right|} = c_{1}x_{1} + c_{2}\left(\frac{\lambda_{2}}{\lambda_{1}}\right)^{k}x_{2} + c_{3}\left(\frac{\lambda_{3}}{\lambda_{1}}\right)^{k}x_{3} + \ldots + c_{n}\left(\frac{\lambda_{n}}{\lambda_{1}}\right)^{k}x_{n} \quad \text{converges to } c_{1}x_{1}.$

The largest ratio controls the convergence when k is large, it is nothing but $\frac{\lambda_n}{\lambda_{n-1}}$.

 $A = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ is the suitable matrix such that $|\lambda_1| = |\lambda_2|$ and has no convergence.

$$\boxed{\frac{u_k}{\lambda_n^k} = c_1 x_1 + c_2 \left(\frac{\lambda_2}{\lambda_1}\right)^k x_2 + c_3 \left(\frac{\lambda_3}{\lambda_1}\right)^k x_3 + \ldots + c_n \left(\frac{\lambda_n}{\lambda_1}\right)^k x_n \to c_1 x_1 \text{if } \frac{|\lambda_i|}{|\lambda_1|} < 1 \text{ for every } i.}$$

The largest ratio controls the convergence when k is large.

$$A = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$$
 has $|\lambda_1| = |\lambda_2|$ and no convergence.

Therefore
